

# Optimizing a PoS Tag Set for Dependency Parsing

Anonymous ACL submission

## Abstract

Abstraction ensues.

## 1 Introduction

Part-of-speech (PoS) tagging is an important preprocessing step for many NLP tasks, such as dependency parsing (Nivre et al., 2007; Hajič et al., 2009), named entity recognition (Sang and Meulder, 2003) and sentiment analysis (Wilson et al., 2009). Whereas much effort has gone into the development of PoS-taggers – to the effect that this task is often considered more or less a solved task – considerably less effort has been devoted to the empirical evaluation of the PoS tag sets themselves. Error analysis of PoS taggers indicate that, whereas tagging improvement through means of learning algorithm or feature engineering seems to have reached something of a plateau, linguistic and empirical assessment of the distinctions made in the PoS tag sets may be a venue worth investigating further (Manning, 2011). Clearly, the utility of a PoS tag set is tightly coupled with the downstream task for which it is performed. Even so, PoS tag sets are usually employed in a “one size fits all” fashion, regardless of the requirements posed by the task which makes use of this information.

It is well known that syntactic parsing often benefits from quite fine-grained morphological distinctions (Zhang and Nivre, 2011; Seeker and Kuhn, 2013). Morphology interacts with syntax though phenomena such as agreement and case marking, and incorporating information on morphological properties of words can therefore often improved parsing performance. However, in a realistic setting where the aim is to automatically parse raw text, the generation of morphological information will often require a separate step of morphological analysis that can be quite costly.

In this paper, we optimize a PoS tag set for the task of data-driven dependency parsing of Norwegian. We report on a set of experiments where various morphological distinctions are introduced to the PoS annotations and evaluated both intrinsically, i.e., in terms of PoS tagging accuracy, and extrinsically, in terms of parsing accuracy. Our results show that the introduction of morphological distinctions not present in the original tag set, whilst compromising tagger accuracy, actually leads to significantly improved parsing accuracy. This optimization allows us to bypass the additional step of morphological analysis, framing the whole preprocessing problem as a simple tagging task.

The article is structured as follows. We start out by reviewing previous work on tag set evaluation in Section 2, while Section 3 details the treebank that provides the initial gold annotations used for our experiments. Section 4 describes the experimental setup used in our work and Section 5 goes on to provide the results from our tag set optimization. Finally, Section 6 summarizes our main findings and discusses some avenues for future work.

## 2 Previous Work

There has been little previous work dedicated specifically to extrinsic evaluation of the effects of PoS tag sets on downstream applications. There has, however, been some work that evaluates the effects of PoS tag set granularity on PoS tagging. This includes investigation of the effects of PoS tag sets on tagging of Swedish (Megyesi, 2001; Megyesi, 2002) and English (MacKinlay, 2005).

Megyesi (2002) trained and evaluated a range of PoS taggers on the Stockholm-Umeå Corpus (SUC) (Gustafson-Capková and Hartmann, 2006), annotated with a tag set based on a Swedish version of PAROLE tags totaling 139 tags. Further-

more, they investigated the effects of tag set size on tagging by mapping the original tag set into smaller subsets designed for parsing. They argue that a tag set with complete morphological tags may not be necessary for all NLP applications, for instance syntactic parsing. They found that the smallest tag set comprising 26 tags yields the lowest tagger error rate. However, for some of the taggers, augmenting the tag set with more linguistically informative tags may actually lead to a drop in error rate. They argue that this shows that the size of the tag set as well as the type of information in the tags are crucial factors for tagger performance. However/unfortunately, they do not report results of parsing with the various PoS tag sets.

Similarly, MacKinlay (2005) investigated the effects of PoS tag sets on tagger performance in English, specifically the Wall Street Journal portion of Penn Treebank (Marcus et al., 1993). They mapped the original tag set of Penn Treebank comprising 45 tags to more fine-grained tag sets using linguistic insight to investigate whether additional linguistic information included in finer-grained tags could assist the tagger. Experimenting with both lexically and syntactically conditioned modifications such as distinguishing between count nouns and noncount nouns and between transitive and intransitive verbs, they found that more fine-grained tag sets rarely led to improvements in tagger accuracy; the most successful modification yielded an improvement in tagger accuracy of 0.05 percentage points. They did not find any statistically significant improvements using linguistically informed distinctions, arguing that their results do not support the hypothesis that it is possible to achieve significant performance improvements in PoS tagging by utilizing a finer-grained tag set.

### 3 The Norwegian Dependency Treebank

We used the newly developed Norwegian Dependency Treebank (NDT) (Solberg et al., 2014), the first publicly available treebank for Norwegian. It was developed at the National Library of Norway in collaboration with the University of Oslo, and contains manual syntactic and morphological annotation. The treebank contains data from both varieties of Norwegian; 311 000 tokens of Bokmål and 303 000 tokens of Nynorsk. We will in the

following only be using the Bokmål portion of the treebank. The annotated texts are mostly newspaper text, but also include government reports, parliament transcripts and excerpts from blogs. The annotation process of the treebank was supported by the rule-based Oslo-Bergen Tagger (Hagen et al., 2000) and then manually corrected by annotators, adding syntactic dependency analysis to the morphosyntactic annotation.

**Morphological Annotation** The morphological annotation and PoS tag set of NDT follows the Oslo-Bergen Tagger (Hagen et al., 2000; Solberg, 2013), which in turn is largely based on the work of Faarlund et al. (1997). The tag set consists of 12 morphosyntactic PoS tags outlined in Table 1, with 7 additional tags for punctuation and symbols. The tag set is thus rather coarse-grained, with broad categories such as *subst* (noun) and *verb* (verb). The PoS tags are complemented by a large set of morphological features, providing information about morphological properties such as definiteness, number and tense. These features are used in our tag set modifications, where the coarse PoS tag of relevant tokens is concatenated with one or more of these features to include more linguistic information in the tags.

**Syntactic Annotation** The syntactic annotation choices in NDT are largely based on the Norwegian Reference Grammar (Faarlund et al., 1997). The annotation choices are outlined in Table 2, taken from/courtesy of Solberg et al. (2014), providing overview of the analyses of syntactic constructions that often distinguish dependency treebanks, such as coordination and the treatment of auxiliary and main verbs. The set of dependency relations comprises 29 dependency relations, including ADV (adverbial), SUBJ (subject) and KO-

Head	Dependent

ORD (coordination).

## 4 Experimental Setup

In preparation to conducting our experiments with linguistically motivated tag set modifications, a concrete setup for the experiments needed to be established, which is presented in the following.

Our approach is somewhat semi-automatic in that we employ a "hybrid" combination of manual annotation and automatic labeling in our experiments. Our initial tags are gold standard, and using linguistic insight coupled with computational considerations, we introduce new gold standard distinctions to the tag set. The data sets with these tags are run through a pipeline with automatically assigned tags in both training and testing, where the most promising modifications are used "further". Hence, the tag set modifications are not deterministic, nor do we try all possible combination; we only experiment with linguistically motivated distinctions. We are in reality altering the gold standard tags by the addition of more linguistic information.

As we want to investigate how we can improve the linguistic quality of a tag set, we will only consider tag set modifications we deem linguistically sensible.

**Data Set Split** As there was no standardized data set split of NDT due to its very recent development, we needed to establish a data set split (training/development/test). Our data set split of the treebank follows the standard 80-10-10 (training/development/test) split and will be distributed with the treebank and proposed as the new standard(?). In creating the data set split, care has been taken to preserve contiguous texts in the various data sets while keeping the split balanced in terms of genre. Our proposed data set split was used in the Norwegian contribution to the Universal Dependencies project (Øvrelid and Hohle, 2016). The split will be made available at a companion website. In our experiments, we train on

the training data and evaluate on the development data, before finally evaluating our optimized tag set on the held-out test data set.

**Tagger** For our experiments with tag set modifications, we sought a PoS tagger both reasonably fast and accurate. There is often a considerable trade-off between the two factors, as the most accurate taggers tend to suffer in terms of speed due to their complexity. However, a tagger that achieves both close to state-of-the-art accuracy as well as very high speed is TnT (Brants, 2000). TnT was furthermore recently used to evaluate the recently proposed universal tag set (Petrov et al., 2012). The sum of these factors led to TnT being the tagger of choice for our experiments.

**Parser** In choosing a syntactic parser for our experiments, we considered previous work on dependency parsing of Norwegian, specifically that of Solberg et al. (2014), who found the Mate parser (Bohnet, 2010) to be the most successful parser for parsing of NDT. Furthermore, recent dependency parser comparisons (Choi et al., 2015) showed that Mate performed very well on parsing of English, beating a range of contemporary state-of-the-art parsers. Mate was consequently selected to evaluate the tag set modifications in our experiments.

**Tag Set Mapping** The tag set modifications are realized by mapping the existing tags to new, more fine-grained tags "based" on associated morphological features to be included in specified tags. The procedure maps the relevant existing tags to new, more fine-grained tags including more relevant morphological features for the applicable tokens, i.e., tokens that are assigned said tag and feature(s) in the gold standard data. Hence, we are in actuality altering the gold standard tags by the addition of more relevant linguistic information, producing new gold standard annotations of higher quality.

**Evaluation** To evaluate tagging and parsing with the various tag set modifications in our experiments, we employed commonly used evaluation metrics. Tagging is evaluated in terms of accuracy (reported by the TnT-included `tnnt-diff` script), while labeled attachment score (LAS) and unlabeled attachment score (UAS) are computed by the `eval.pl`<sup>1</sup> script (used in the CoNLL shared

<sup>1</sup><http://ilk.uvt.nl/conll/software.html>

Training	Testing	LAS	UAS
Gold	Gold	90.15%	92.51%
Gold	Auto	85.68%	88.98%
Auto	Auto	87.01%	90.19%

Table 3: Results of parsing with Mate using the various tag configurations, either using gold standard tags or automatically assigned from TnT. *Gold* denotes gold standard tags, *Auto* denotes automatically assigned tags from TnT.

tasks) to evaluate the parsing.

**Baseline** It is common practice to compare the performance of PoS taggers to a pre-computed baseline for an initial point of comparison. For PoS tagging, a commonly used baseline is the Most Frequent Tag (MFT) baseline, which we used in our experiments. This involves labeling each word with the tag it was assigned most frequently in the training. All unknown words, i.e., words not seen in the training data, are assigned the tag most frequently assigned to words seen only once in the training. Unknown and infrequent words have in common that they rarely occur, and we might therefore expect them to have similar properties.

**Tags & Features** As we seek to quantify the effects of PoS tagging in a realistic setting, i.e., in application to raw text, we want to evaluate the parser on automatically assigned PoS tags. For the training of the parser, however, we have two options: using either gold standard or automatically assigned tags. In order to settle on a configuration, we conducted experiments with gold standard and automatically assigned tags to see how they differ with respect to performance. The results of these experiments, shown in Table 3, reveal that the combination of training and testing on automatic tags is clearly superior to training on gold standard tags and testing on automatic tags. Consequently, the parser was both trained and tested on automatically assigned tags in our experiments.

We removed any morphological features in order to simulate a realistic setting. Moreover, it is crucial that we remove these features when working with automatically assigned tags, as the features are still gold standard. For instance, if a verb token is erroneously tagged as a noun, we could potentially have a noun token with verbal features such as tense, which markedly obfuscates the training and parsing. Another important as-

pect is that we want to isolate the effect of PoS tags, necessitating the exclusion of morphological features.

In the following, we report on a set of experiments which evaluate increasingly fine-grained PoS tag sets. The PoS tag sets are motivated by morphosyntactic properties of Norwegian and are evaluated in terms of both tagger and parser accuracy.

## 5 Tag Set Optimization

By introducing more fine-grained linguistically motivated distinctions in a tag set, we increase the linguistic information represented in the tags, which may assist the parser in recognizing and generalizing syntactic patterns. However, the addition of more linguistic information to the tags and thus a more fine-grained tag set will most likely lead to a drop in tagger accuracy due to the increase in complexity. The best tagging does not necessarily lead to the best parse, hence it is interesting to investigate how linguistically informed tag set modifications may affect the interplay between tagging and parsing.

### 5.1 Baseline Experiments

In an initial round of experiments, we concatenated the tag of each token with its set of morphological features in order to map the original tag set to a new, more fine-grained tag set (hereafter referred to as the *full* tag set). This resulted in a total of 368 tags, which is clearly very fine-grained. The two initial tag sets, i.e., the original tag set comprising 19 tags and the full tag set comprising 368 tags, thus represent two extremes in terms of granularity. To evaluate the initial tag sets and investigate how the tag set granularity would affect the performance of tagging and parsing, we ran baseline experiments with the two tag sets. In Table 4, we report the results of these experiments. We see that the tagger accuracy drastically drops when going from the original to the full tag set. TnT reports an accuracy of 97.47% on the original tag set, which is reduced to 93.48% for the full tag set. These results confirm our hypothesis that the very high linguistic quality in the full, fine-grained tag set comes at the expense of drops in tagger performance. However, the additional linguistic information provided by the full tag set improves the parser performance. With the original tag set, Mate reports an LAS of 87.01% and

Tag Set	Acc	LAS	UAS
Original	<b>97.47%</b>	87.01%	90.19%
Full	93.48%	<b>87.15%</b>	<b>90.39%</b>

Table 4: Results of tagging and parsing with the two initial tag sets.

a UAS of 90.19%, which increases to 87.15% and 90.39%, respectively, using the full tag set. As we are looking for linguistically informed distinctions that improve the syntactic parsing, these results are promising and serve to indicate that additional linguistic information assists the syntactic parsers, motivating the optimization of the existing PoS tag set.

## 5.2 Tag Set Experiments

We modified the tags for nouns (*subst*), verbs (*verb*), adjectives (*adj*), determiners (*det*) and pronouns (*pron*) in NDT by appending selected sets of morphological features to each tag in order to increase the linguistic information expressed by the tags. For each tag, we first experimented with each of the available features in isolation before employing various combinations of them. We based our choices of combinations on how promising the features are and what we deem worth investigating in terms of linguistic utility, in order to see how the features might interact.

The morphological properties of the various parts-of-speech are reflected in the morphological features associated with the respective PoS tags. For instance, as nouns in Norwegian can take on gender, definiteness and number, additionally marked with genitive case, the treebank operates with features for gender, definiteness, number and case. In addition to morphological properties such as definiteness, tense and number, all classes except for verbs have a *type* feature that provides information about the subtype, e.g., common nouns and proper nouns, while pronouns can be reflexive, reciprocal, personal or interrogative.

**Nouns** In Norwegian, nouns are assigned gender (feminine, masculine or neuter), definiteness (definite or indefinite) and number (singular or plural). There is agreement in gender, definiteness and number between nouns and their modifiers (adjectives and determiners). Additionally, NDT has a separate case feature for distinguishing nouns in genitive case.

As nouns constitute the largest class in the tree-

Feature(s)	Acc	LAS	UAS
—	97.47%	87.01%	90.19%
Case	<b>97.48%</b>	87.63%	90.72%
Definiteness	97.00%	88.27%	91.42%
Gender	96.09%	87.21%	90.36%
Number	96.37%	87.97%	91.00%
Type	96.92%	88.07%	91.11%
Case & definiteness	97.03%	88.39%	91.44%
Type & case	96.92%	88.46%	91.51%
Type & definiteness	96.99%	88.44%	91.48%
Type, case & definiteness	97.05%	<b>88.81%</b>	<b>91.73%</b>

Table 5: Results of experiments with modified PoS tags for nouns.

bank by far, the effects are greatest for noun tokens in terms of overall change in performance. The results of experimenting with tag set modifications for nouns are shown in Table 5, and reveal that, apart from case, none of the tag set modifications improves the tagging. However, they all give rise to increases in parser accuracy scores. Genitive case marks possession, hence nouns marked with genitive case are quite different from other nouns, taking a noun phrase as complement. Distinguishing on type is useful and informative, as evident by the presence of separate tags for proper and common nouns in many tag sets, such as those of Penn Treebank and Stockholm-Umeå corpus.

The most informative features are definiteness, which leads to an increase in LAS by 1.26 percentage points to 88.27%, and type, yielding an LAS of 88.07%. Turning to combinations of features, we found that the combination of type and case, as well as type and definiteness, were the most promising, which led us to combine type, case and definiteness in a final experiment, resulting in LAS of 88.81% and UAS of 91.73%, constituting large increases from parsing with the original tag set, by 1.80 percentage points and 1.54 percentage points, respectively.

**Verbs** Verbs are inflected for tense (infinitive, present, preterite, past perfect) in Norwegian and additionally exhibit mood (imperative, indicative) and voice (active or passive). Note that both voice and mood have only a single value in the treebank, *pass* (passive) and *imp* (imperative), respectively. Verbs which are not passive are implicitly active, and verbs which are not imperative are indicative.

Table 6 presents the results from tagging and parsing with modified verb tags. Introducing fea-

Feature(s)	Acc	LAS	UAS
—	<b>97.47%</b>	87.01%	90.19%
Mood	97.43%	87.04%	90.19%
Tense	97.30%	86.97%	90.18%
Voice	97.45%	86.96%	90.09%
Mood & tense	97.31%	87.12%	90.31%
Voice & tense	97.28%	86.99%	90.15%
Mood, tense & voice	97.27%	86.83%	90.05%
Finiteness	97.35%	<b>87.30%</b>	<b>90.43%</b>

Table 6: Results of experiments with modified PoS tags for verbs.

tures in isolation, mood is the only feature leading to an increase in LAS, with a reported LAS of 87.04%. Imperative clauses are fundamentally different from indicative clauses, as they lack an overt subject. Although voice is a very distinguishing property for verbs, and passive verbs appear in clauses very different from those with active verbs, introducing this distinction in the tag set leads to a drop in LAS of 0.05 percentage points. Distinguishing between the various tenses yields an LAS of 86.97%. Combining the two most promising features, mood and tense, resulted in an LAS of 87.12% and UAS of 90.31%.

In an additional experiment, we mapped the verb tenses (and mood, in the case of imperative) to finiteness. All verbs have finiteness, hence this distinction has broad coverage. This mapping is syntactically grounded as finite verbs and nonfinite verbs appear in completely different syntactic constructions, and proved to greatly improve the parsing, as we saw the overall largest parser accuracy scores, with 87.30% for LAS and 90.43% for UAS, 0.29 and 0.24 percentage points higher than the baseline, respectively. This coincides with the observations seen for Swedish in Øvreliid (2008), where finiteness was found to be a very beneficial linguistic feature for parsing.

**Adjectives** Adjectives agree with the noun they modify in terms of gender, number and definiteness in Norwegian. Adjectives are also inflected for degree (positive, comparative or superlative).

In Table 7, we report the results of modifying the `pron` tag in NDT. All features except for number led to increases in parser accuracy scores, the most successful of which is degree with a reported LAS of 87.29%, while distinguishing adjectives on definiteness yield an LAS of 87.14% and gender leads to LAS of 87.10%.

Turning to combinations of features, definite-

Feature(s)	Acc	LAS	UAS
—	<b>97.47%</b>	87.01%	90.19%
Definiteness	96.84%	87.14%	90.29%
Degree	97.41%	<b>87.29%</b>	<b>90.44%</b>
Gender	96.89%	87.10%	90.25%
Number	96.71%	86.99%	90.10%
Type	97.40%	87.11%	90.25%
Definiteness & degree	96.81%	87.23%	90.39%
Definiteness & gender	96.31%	87.18%	90.39%
Definiteness & number	96.78%	87.27%	<b>90.44%</b>

Table 7: Results of experiments with modified PoS tags for adjectives.

ness and number achieve the best results, very close to that of degree, with 0.02 percentage points lower LAS and identical UAS. Adjectives agree with their head noun and determiner in definiteness and number, making this an expected improvement. The combination of definiteness and degree is also quite promising, obtaining LAS of 87.23% and UAS of 90.39%. It is interesting that none of the combinations surpass the experiment with degree alone, which indicates that degree does not interact with the other features in any syntactically significant way.

**Determiners** Like adjectives, determiners in Norwegian agree with the noun they modify in terms of gender, number and definiteness. Possessive pronouns are treated/analyzed as determiners in NDT.

The results from the experiments with determiners are shown in Table 8. Introducing the distinction of type led to an increase in tagger accuracy by 0.14 percentage points to 97.61%, while marginally impacting the parsing, with LAS of 87.00%, 0.01 percentage points below that of the original tag set. The increase in tagger accuracy when introducing the distinction of type is noteworthy, as we expected the finer granularity to lead to a decrease in accuracy. This serves to indicate that more fine-grained distinctions for determiners, which is a quite disparate category in the treebank, may be quite useful for tagging. However, as it has negative impact on the syntactic parsing, we can conclude that the type of a determiner does not assist in generalizing syntactic patterns, as most determiners, regardless of type, appear in the same syntactic constructions (i.e., before a noun or noun phrase).

Gender, on the other hand, improved the parsing, but complicated the tagging, as the various genders are often difficult to differentiate, espe-

Feature	Acc	LAS	UAS
—	97.47%	87.01%	90.19%
Definiteness	97.49%	<b>87.30%</b>	<b>90.42%</b>
Gender	97.28%	87.09%	90.31%
Number	97.49%	87.04%	90.18%
Type	<b>97.61%</b>	87.00%	90.11%

Table 8: Results of experiments with modified PoS tags for determiners.

cially so in the case of masculine and feminine, which share many of the same determiners. The number of a determiner, i.e., singular or plural, led to a small increase in tagger accuracy and LAS, while marginally lower UAS, 90.18%, 0.01 percentage points lower than that of the original tag set. The introduction of definiteness to the determiners led to the best parsing results, LAS of 87.30% and UAS of 90.42%, while also increasing the tagger accuracy slightly. The increase in LAS and UAS is rather interesting, as there are only 121 determiner tokens with marked definiteness in the development data. As this accounts for a very small number of tokens, we did not consider further fine-grained modifications with definiteness. This goes to show that tokens with overt definiteness have noticeable impact on the syntactic parsing, and that distinguishing on definiteness is very beneficial.

**Pronouns** Pronouns in Norwegian include personal, reciprocal, reflexive and interrogative. They can exhibit gender, number and person. Personal pronouns have case (accusative or nominative).

The results in Table 9 show that number, person and type are the most informative features for parsing, with LAS of 87.21%, 87.22% and 87.19%, respectively. However, when combining number and person, we observe a drop by more than 0.2 percentage points, indicating that these features do not interact in any syntactically distinctive way. The most interesting observation is that all experiments exceed the tagging accuracy of the original tag set, the most improved being the most fine-grained distinction, namely type, case and number combined, obtaining a tagger accuracy of 97.52%. This shows that the introduction of more fine-grained distinctions for pronouns is beneficial and aids the PoS tagger in disambiguating ambiguous words. While case alone yields an LAS of 87.08%, we found that the combination of type and case, which is the most successful experiment in terms of parser performance, yields the

Feature(s)	Acc	LAS	UAS
—	97.47%	87.01%	90.19%
Case	97.50%	87.08%	90.21%
Gender	97.48%	87.06%	90.23%
Number	97.49%	87.21%	90.33%
Person	97.49%	87.22%	90.32%
Type	97.48%	87.19%	90.40%
Number & person	97.49%	96.98%	90.16%
Type & case	97.51%	<b>87.30%</b>	<b>90.41%</b>
Type & number	97.49%	87.27%	<b>90.41%</b>
Type & person	97.49%	87.00%	90.14%
Type, case & number	<b>97.52%</b>	87.11%	90.36%

Table 9: Results of experiments with modified PoS tags for pronouns.

second highest tagging accuracy of 97.51%. The reason for this is that pronouns of different type and personal pronouns of different case exhibit quite different properties and appear in different constructions. Pronouns in nominative case (i.e., subjects) primarily occur before the main verb, while pronouns in accusative case (i.e., objects) occur after the main verb, as Norwegian exhibits so-called V2 word order, requiring that the finite verb of a declarative clause appears in the second position, hence its name. The combination of type and number comes in close to the performance of type and case, with LAS of 87.27% and UAS identical to that of type and case.

### 5.3 Optimized Tag Set

The most successful tag set modification for each PoS and their results are seen in Table 10. Nouns benefit by far the most from the introduction of more fine-grained linguistically motivated distinctions, with an LAS of 88.81% and UAS of 91.73%. We observe that the most promising tag set modifications for verbs, adjectives, determiners and pronouns all reach LAS of ~87.30% and UAS of ~90.40%. To investigate the overall effect of these tag set modifications, we tested each of the improvements in parser accuracy scores from baseline for statistical significance using Dan Bikel’s randomized parsing evaluation comparator script<sup>2</sup>, as used in the CoNLL shared tasks. For the most successful tag set modification for each of the categories seen in Table 10, the difference in LAS from the original tag set is statistically significant at significance level 0.05 ( $p$ -value < 0.05), as are all differences in UAS, except for verbs with finiteness ( $p$ -value 0.15) and pronouns with type

verb infin	Nonfinite verb

Table 11: Overview of the optimized tag set.

and case ( $p$ -value 0.06).

An overview of the tags in the optimized tag set can be seen in Table 11, comprising three new tags for adjectives, two for determiners, six for pronouns, seven for nouns and two for verbs, totaling 20 tags. Appending these to the original tag set comprising 19 tags, we reach a total of 39 tags for NDT.

**Final Evaluation** In Table 12, we show the results of parsing with the optimized tag set on the held-out test set, compared to the results obtained with the original tag set. We see significant improvements from the original tag set on both the development data and the held-out test data set. The improvement in LAS on the development data is 1.86 percentage points, while 1.91 percentage points on the held-out test data. These results indicate that the additional linguistic information in the tags of our optimized tag set greatly aids syntactic parsing and that optimizing an existing PoS tag set for a downstream application can be useful and beneficial.

Data	Tag Set	Acc	LAS	UAS
Dev	Original	<b>97.47%</b>	87.01%	90.19%
	Optimized	96.85%	<b>88.87%</b>	<b>91.78%</b>
Test	Original	<b>97.30%</b>	86.64%	90.07%
	Optimized	96.35%	<b>88.55%</b>	<b>91.41%</b>

Table 12: Results of tagging and parsing with the optimized tag set, compared to the initial tag sets. Trained and tested using automatically assigned tags from TnT.

## 6 Summary and Future Work

The improvements in parser performance with our optimized tag set indicate that a more fine-grained PoS tag set may assist syntactic parsers in recognizing and generalizing syntactic patterns, while potentially compromising the performance of PoS taggers.

There are several aspects of this thesis that can be further explored in future work, including extrinsic evaluation of the effects of PoS tag sets on other downstream NLP applications besides parsing, such as sentiment analysis and named entity recognition. These applications often require tagged data, but are markedly different from syntactic parsing, hence the evaluation would involve investigating an entirely different aspect of the effects of tag set granularity.
